How to read this

- H / A** Home and away win probability. A tie shows as a sliver in the NFL and is impossible in college.
- projected** Projected points, home-away.
- total** Projected combined points.
- spread** Projected margin, quoted on the favourite.
- by 3 / by 7** Chance the final margin lands exactly on 3 or on 7, either way. Read as a floor — see the note below.
- gap** Point differential per game, the distance between the two sides.
- W T L** Last five results, most recent first, with points for and against across them.
- dots** How much rests on these teams' own results: three dots = 4+ games each, none = league baseline.

The quarterback is not in this model

In football the starting quarterback moves a line further than any other single factor — several points on the spread — and the feed carries no depth chart or injury data. A game where a starter is out is under-modelled here.

Weather is absent too, and it matters more in this sport than in any other in this repo. So are rest and travel, including the short week a Thursday game imposes.

Key numbers are a floor, not a figure

Football margins pile up on 3 and 7 because scores are built from field goals and touchdowns. The percentages here come from discretising a smooth normal curve, which spreads that mass evenly and so understates the real clustering.

The ordering is right and the numbers are conservative. Treat a projected margin sitting on 3 or 7 as more dangerous than the figure suggests, not less.
